

NCP5911

IMVP7.0 Compatible Synchronous Buck MOSFET Driver

The NCP5911 is a high performance dual MOSFET gate driver optimized to drive the gates of both high-side and low-side power MOSFETs in a synchronous buck converter. It can drive up to 3 nF load with a 25 ns propagation delay and 20 ns transition time.

Adaptive anti-cross-conduction and power saving operation circuit can provide a low switching loss and high efficiency solution for notebook systems.

A bidirectional Enable pin can provide a fault signal to the controller when the gate driver detects an undervoltage lockout. The UVLO function guarantees the outputs are low when the supply voltage is low.

APPLICATION INFORMATION

The NCP5911 gate driver is a single phase MOSFET driver designed for driving N-channel MOSFETs in a synchronous buck converter topology. The NCP5911 is designed to work with ON Semiconductor's NCP6131 multi-phase controller. This gate driver is optimized for notebook applications.

Undervoltage Lockout

DRVH and DRVL are held low until VCC reaches 4.5 V during startup. The PWM signal will control the gate status when VCC threshold is exceeded.

Three-State EN Signal

Undervoltage Lockout will de-assert the EN pin, which will pull down the DRON pin of the controller as well.

When EN is set to the mid state, both DRVH and DRVL are set low, to force diode mode operation.

PWM Input and Zero Cross Detect (ZCD)

The PWM input, along with EN and ZCD, control the state of DRVH and DRVL.

When PWM is set high, DRVH will be set high after the adaptive non-overlap delay. When PWM is set low, DRVL will be set high after the adaptive non-overlap delay.

When PWM is set to the mid state, DRVH will be set low, and after the adaptive non-overlap delay, DRVL will be set high. DRVL remains high during the ZCD blanking time. When the timer has expired, the SW pin will be monitored for zero cross detection. After the detection, DRVL will be set low.

Adaptive Non-overlap

Adaptive dead time control is used to avoid shoot-through damage of the power MOSFETs. When the PWM signal pulls high, DRVL will be set low and the driver will monitor the gate voltage of the low side MOSFET. When the DRVL

voltage falls below the gate threshold, DRVH will be set to high after the $t_{pdhDRVH}$ delay. When PWM is set low, the driver will monitor the gate voltage of the high side MOSFET. When the DRVH-SWN voltage falls below the top gate drive threshold, DRVL will be set to high after the $t_{pdhDRVL}$ delay.

Layout Guidelines

The layout for a DC-DC converter is very important. The bootstrap and VCC bypass capacitors should be placed close to the driver IC.

Connect the GND pin to a local ground plane. The ground plane can provide a good return path for gate drives and reduce the ground noise. The thermal slug should be tied to the ground plane for good heat dissipation. To minimize the ground loop for the low side MOSFET, the driver GND pin should be close to the low-side MOSFET source pin. The gate drive trace should be routed to minimize its length. The minimum width is 20 mils.

Gate Driver Power Loss Calculation

The gate driver power loss consists of the gate drive loss and quiescent power loss.

The equation below can be used to calculate the power dissipation of the gate driver. Q_{GMF} is the total gate charge for each main MOSFET and Q_{GSF} is the total gate charge for each synchronous MOSFET.

$$P_{DRV} = \left[\frac{f_{SW}}{2 \times n} \times (n_{MF} \times Q_{GMF} + n_{SF} \times Q_{GSF}) + I_{CC} \right] \times V_{CC} \quad (\text{eq. 1})$$

Also shown is the standby dissipation factor ($I_{CC} \times V_{CC}$) of the driver.
